(54) Title: DENTAL RESTORATIVE MATERIALS

(57) Abstract: The present invention relates to a composition for dental restoration including a dental restorative material and an effective amount of a casein phosphopeptide(CPP)-amorphous calcium phosphate (ACP) complex or casein phosphopeptide(CPP)-amorphous calcium fluoride phosphate (ACFP) complex.

WO 02/094204 A1

DENTAL RESTORATIVE MATERIALS

The present invention relates to dental restorative materials including amorphous calcium phosphates and/or amorphous calcium fluoride phosphates stabilised by phosphopeptides. These dental restorative materials have superior anticariogenic properties protecting tooth structures as they remineralise (repair) early stages of dental caries that may have developed around the restoration. Methods of making the dental restorative materials of the invention and of treatment or prevention of dental caries are also provided. The invention also provide a kit of parts including amorphous calcium phosphates and/or amorphous calcium fluoride phosphates stabilised by phosphopeptides.

BACKGROUND

Dental caries is initiated by the demineralisation of hard tissue of the teeth by organic acids produced from fermentation of dietary sugar by dental plaque odontopathogenic bacteria.

Dental caries is still a major public health problem and restored tooth surfaces can be susceptible to further dental caries around the margins of the restoration.

Casein phosphopeptide-amorphous calcium phosphate complexes (CPP-ACP) and CPP-stabilised amorphous calcium fluoride phosphate complexes (CPP-ACFP) in solution have been shown to prevent enamel demineralisation and promote remineralisation of enamel subsurface lesions in animal and human *in situ* caries models [Reynolds 1997 patent application, PCT/AU98/00160].

The active CPP have been specified in the US Patent No. 5,015,628 and include peptides Bos α_{s1} -casein X-5P (f59-79) [1], Bos β -casein X-4P (f1-25) [2], Bos α_{s2} -casein X-4P (f46-70) [3] and Bos α_{s2} -casein X-4P (f1-21) [4] as follows:

[1] Gln⁵⁹-Met-Glu-Ala-Glu-Ser(P)-Ile-Ser(P)-Ser(P)-Ser(P)-Glu-Glu-Ile-Val-Pro-Asn-Ser(P)-Val-Glu-Gln-Lys⁷⁹. α_{s1} (59-79)

[2] Arg¹-Glu-Leu-Glu-Glu-Leu-Asn-Val-Pro-Gly-Glu-Ile-Val-Glu-Ser(P)-Leu-Ser(P)-Ser(P)-Ser(P)-Glu-Glu-Ser-Ile-Thr-Arg²⁵. β (1-25)

[3] Asn⁴⁶-Ala-Asn-Glu-Glu-Glu-Tyr-Ser-Ile-Gly-Ser(P)-Ser(P)-Ser(P)-Glu-Glu-Ser(P)-Ala-Glu-Val-Ala-Thr-Glu-Glu-Val-Lys⁷⁰. $\alpha_{s2}(46-70)$

[4] Lys¹-Asn-Thr-Met-Glu-His-Val-Ser(P)-Ser(P)-Ser(P)-Glu-Glu-Ser-Ile-Ile-Ser(P)-Gln-Glu-Thr-Tyr-Lys²¹. $\alpha_{s2}(1-21)$

These peptides stabilise novel forms of very soluble amorphous calcium phosphate and amorphous calcium fluoride phosphate [Reynolds 1997 patent application, PCT/AU98/00160].

10 Glass ionomer cements (GICs) are water-based, tooth coloured and chemically adhesive materials used in dentistry as bases and restorations. Microleakage around restorations remains a significant problem, which can lead to caries of the underlying tooth tissues (Bergenholtz *et al.*, 1982; Davis *et al.*, 1993; Pachuta and Meiers, 1995). However, GICs are ion-releasing materials and the
15 incorporation and slow release of fluoride ions from the cement provides a significant anticariogenic property (Forss, 1993; Williams *et al.*, 1999)

Although it would be expected that inclusion of CPP-ACP into a GIC would result in the incorporation of the calcium ions into the GIC matrix making them unavailable, surprisingly, we have discovered that incorporation of CPP-ACP into a
20 standard, commercially-available GIC resulted in a GIC with unexpected superior properties in terms of microtensile bond strength. Comprehensive strength and ion-release. In fact, surprisingly the GIC containing CPP-ACP was able to significantly remineralize the underlying dentine whereas the standard GIC could not. These results form the basis of this invention which is novel dental restorative materials
25 containing CPP-ACP or CPP-ACFP with superior physicochemical and anticariogenic properties.

SUMMARY OF THE INVENTION

The present invention relates to a composition for dental restoration including
30 a dental restorative material and an effective amount of a casein phosphopeptide(CPP)-amorphous calcium phosphate (ACP) complex or casein phosphopeptide(CPP)-amorphous calcium fluoride phosphate (ACFP) complex.

According to one aspect of the invention, there is provided a composition for dental restoration, including a dental restorative material to which has been added amorphous calcium phosphate (ACP) or amorphous calcium fluoride phosphate (ACFP) stabilized by phosphopeptides containing the amino acid sequence –
5 Ser(P)-Ser(P)-Ser(P)-. Preferably, the ACP and ACFP are formed under alkaline conditions. The amorphous calcium phosphate is preferably of the approximate formula $\text{Ca}_3(\text{PO}_4)_2 \cdot x\text{H}_2\text{O}$ where $x \geq 1$, ie there are one or more H_2O per $\text{Ca}_3(\text{PO}_4)_2$. The calcium phosphate derivative may be a calcium fluoride phosphate of approximate formula $\text{Ca}_2\text{F}(\text{PO}_4) \cdot x\text{H}_2\text{O}$ where $x \geq 1$ providing amorphous calcium
10 fluoride phosphate (ACFP). More preferably the calcium phosphate derivative may be a mixture of ACP and ACFP in the ratio $n:1$, where n is an integer ≥ 1 , eg 1:1 giving $\text{Ca}_5\text{F}(\text{PO}_4)_3$ or 2:1 giving $\text{Ca}_8\text{F}(\text{PO}_4)_5$.

It is expected that the exact ratios described above, and the proportions of components in the amorphous calcium phosphate, will be different in the final
15 composition due, for example, to interactions between components.

The phosphopeptide may be from any source; it may be obtained by tryptic digestion of casein or other phospho-acid rich proteins or by chemical or recombinant synthesis, provided that it comprises the core sequence -Ser(P)-Ser(P)-Ser(P)-. The sequence flanking this core sequence may be any sequence.
20 However, those flanking sequences in $\alpha_{s1}(59-79)$ [1], $\beta(1-25)$ [2], $\alpha_{s2}(46-70)$ [3] and $\alpha_{s2}(1-21)$ [4] are preferred. The flanking sequences may optionally be modified by deletion, addition or conservative substitution of one or more residues. The amino acid composition and sequence of the flanking region are not critical as long as the conformation of the peptide is maintained and that all phosphoryl and caboxyl
25 groups interacting with calcium ions are maintained as the preferred flanking regions appear to contribute to the structural action of the motif.

The base of the dental restorative material can be a glass ionomer cement, a composite material or any other restorative material which is compatible. It is preferred that the amount of CPP-ACP complex or CPP-ACFP complex included in
30 the dental restorative material is 0.01-80% by weight, preferably 0.5-10% and more preferably 1-5% by weight. The dental restorative material of this invention which contains the above mentioned agents may be prepared and used in various forms applicable to dental practice. The dental restorative material according to this

invention may further include other ions, eg. antibacterial ions Zn^{2+} , Ag^+ , etc or other additional ingredients depending on the type and form of a particular dental restorative material. It is preferable that the pH of the CPP-ACP complex or CPP-ACFP complex be between 2-10, more preferably 5-9 and even more preferably 7-9. It is preferable that the pH of the dental restorative material containing the CPP-ACP complex or ACFP complex be between 2-10, more preferably 5-9 and even more preferably 7-9.

The invention is also directed to a method of manufacture of a restorative composition. Preferably, the method includes the addition of ACP and/or ACFP, stabilised by phosphopeptides as stated above, to a base dental restorative material.

The invention also relates to use of a restorative composition as stated above for the treatment and/or prevention of dental caries.

The invention also provides a method of treatment and/or prevention of dental caries in animals including providing the composition according to the invention or manufactured according to the invention and applying to teeth in an animal in need of treatment and/or prevention.

The invention also relates to a kit of parts including (a) dental restorative material and (b) CPP-ACP complex or CPP-ACFP complex together with instructions for their use for the preparation of a composition for dental restoration.

The invention also relates to a kit of parts including (a) dental restorative material (b) casein phosphopeptide (c) calcium ions and (d) phosphate ions, and optionally fluoride ions, together with instructions for their use for the preparation of a composition for dental restoration.

It will be clearly understood that, although this specification refers specifically to applications in humans, the invention is also useful for veterinary purposes. Thus in all aspects the invention is useful for domestic animals such as cattle, sheep, horses and poultry; for companion animals such as cats and dogs; and for zoo animals.

Figure 2 : Longitudinal section of root of tooth restored with GIC containing CPP-ACFP, treated with acid buffer solution and visualised using polarized-light microscopy.

5 **DETAILED DESCRIPTION OF THE INVENTION**

The invention will now be described in detail by way of reference only to the following non-limiting Examples.

Example 1 Incorporation of CPP-ACP into a Glass Ionomer Cement

10 *Preparation of GIC containing CPP-ACP for Compressive Strength and Wet Setting Time assays*

Twenty-four cylinders, 4 mm diam x 6 mm long, were made from a glass ionomer cement (GICs) for the compressive strength test and twelve discs, 10 mm diam x 5 mm thick, for the net setting time test. Four groups (A, B, C, D) were
15 formed with the specimens (Table 1). Six specimens per group were made for the compressive strength test and three specimens per group for the net setting time test.

Group A (control) was prepared using a self-curing glass ionomer cement (Fuji IX GP, liquid batch No. 080561 and powder batch No. 061051, GC
20 International, Tokyo, Japan). Groups B, C and D were prepared from the same GIC, containing 0.78, 1.56 and 3.91 % w/w CPP-ACP respectively incorporated at a powder:liquid ratio of 3.6:1. The CPP-ACP (Recaldent™) was obtained from Bonlac foods Ltd (Melbourne, Australia). For the experimental groups, the CPP-ACP and the GIC powders were manually mixed and shaken in a plastic container, and kept
25 at 4°C until the preparation of the specimens. The GIC liquid and the powder:liquid ratio used for all the specimens were as indicated by the commercial manufacturer of the GIC. The product was allowed to reach room temperature before mixing. For all the groups, the powder and the liquid were manually mixed for 20 s and the mixture was then placed into the molds for each corresponding test. Compressive
30 strength and net setting time tests were performed following ISO methods (ISO, 1991).

Microtensile Bond Strength to Dentin

Non-carious human molars stored in saline solution containing thymol were used within two months following extraction. Seventeen bar-shaped specimens, half GIC and half dentin, were prepared using GIC (Fuji IX GP, batch No.9909021, GC International, Japan) containing 1.56% w/w CPP-ACP as described above. Control specimens (n=17) were prepared using the normal GIC. The liquid and the power:liquid ratio for all the specimens remained the same as for the commercial product. Microtensile bond strength tests were performed following a previously described method (Phrukkanon *et al.*, 1998; Tanumiharja *et al.*, 2000), stressing the specimens in tension at a cross-head speed of 1 mm/min until failure. Mean bond strength values were calculated using the standard formula (ISO, 1991), and the fractured specimens observed in a scanning electron microscope (SEM 515; Phillips, Eindhoven, The Netherlands) to assess the mode of failure.

Ion Measurements and CPP Detection

Twelve discs, 6 mm diam x 2 mm thick, were prepared using the experimental GIC formula containing 1.56 % w/w CPP-ACP and twelve controls were prepared from the unmodified GIC. The GIC was mixed, as described above, injected into the molds, condensed and allowed to set at 37°C and 100% RH for 1 h. During setting, the bottom and top of the filled molds were covered by mylar strips and microscope slides under hand pressure. The discs were removed from the molds and placed into individual sealed plastic tubes. Six of the experimental discs were incubated at 37°C in 2 mL deionized water pH 6.9 (Milli-Q Reagent water System, Millipore Corporation), and the other six in 50 mM sodium lactate (Ajax Chemicals, Auburn, NSW) buffer at pH 5.0. The same procedure was followed with the controls. The solutions were changed every 24 h for 3 days and the release of calcium, inorganic phosphate and fluoride ions was measured in each solution. Calcium concentrations were determined using atomic absorption spectrophotometry (Adamson and Reynolds 1995), inorganic phosphate colorimetrically (Itaya and Ui, 1966) and fluoride ion using an ion selective electrode (Ion 85 Radiometer, Copenhagen, Denmark). The release of the ions was expressed as $\mu\text{mol}/\text{mm}^2$ surface area of the GIC exposed.

The presence of CPP in the solutions was determined using Matrix Assisted Laser Desorption/Ionisation – Mass Spectrometry (MALDI-MS) (Voyager-DE, Perseptive Biosystems; Farmingham, MA, USA) with a matrix of 2,5-dehydroxy benzoic acid in 66% water, 33% CH₃CN and 1% formic acid.

5

Statistical Analysis

Data from compressive strength and net setting time tests were subjected to one-way analysis of variance (ANOVA), using least-significant differences (LSD) for the compressive strength and Bonferroni test for the net setting time. Data from the microtensile bond strength were compared using Student's *t* test ($p < 0.05$). Chi squared distribution ($p < 0.05$) was used to detect the mode of failure of fractured specimens. Data from the ion release analyses were compared using Student's *t* test ($p < 0.05$).

15 RESULTS

Compressive Strength and Net Setting Time

Mean values for the compressive strength and net setting times for the GICs are shown in Table 1. The mean compressive strengths for all specimens ranged from 118.3 MPa to 169.6 MPa, with the highest value being obtained for the GIC containing 1.56% CPP-ACP. The mean net setting times ranged from 523s to 186 s, but only specimens containing 3.91% CPP-ACP (Group D) were significantly different from the others.

Microtensile Bond Strength to Dentin

Table 2 shows the mean microtensile bond strength values for the GIC containing 1.56% w/w CPP-ACP and control and the mode of failure for the fractured specimens. A significantly higher bond strength value was found in the CPP-ACP-containing GIC (10.59 ± 4.00 MPa) than in the control (7.97 ± 2.61 MPa). The distribution in the mode of failure as analysed using SEM was also found to be significantly different ($p < 0.05$). Type 2 fracture was more frequent with the CPP-ACP-containing GIC, whereas Type 4 was more frequent with the control (Table 2). The microstructure of the two cements examined by SEM at a 360x magnification seemed generally similar, although there appeared to be a more porous and

roughened fracture surface with the controls relative to the CPP-ACP-containing cements.

Ion and CPP Release

5 Mean values for the release of fluoride, calcium and phosphate in water (pH 6.9) and sodium lactate buffer (pH 5.0) from the GIC containing 1.56% w/w CPP-ACP and the control GIC are shown in Tables 3, 4 and 5. The pattern of fluoride release in water was similar between samples and controls, with the highest release occurring during the first 24 h and a slower but continued release during the next
10 two 24-h periods (Table 3). Fluoride release was significantly higher in the pH 5.0 sodium lactate buffer than in pH 6.9 water for both materials, the CPP-ACP-containing GIC and the control GIC. Significantly higher fluoride release was found with the CPP-ACP-containing GIC than with the control at both pH values (Table 3).

 Calcium release values from the GICs are shown in Table 4. No calcium was
15 released at neutral pH in water either from the CPP-ACP-containing GIC or from the control. Calcium release was found only in the CPP-ACP-containing GIC in the pH 5.0 sodium lactate buffer. The release was low relative to the fluoride but continuous during the three 24 h periods (Table 4).

 Inorganic phosphate release from the GICs in water (pH 6.9) and sodium
20 lactate buffer (pH 5.0) is shown in Table 5. At both pH values phosphate release was significantly higher from the CPP-ACP-containing GIC than from the controls during the first 24-h period. The release of inorganic phosphate was significantly higher in sodium lactate buffer at pH 5.0 than in water at pH 6.9 for both materials.

 MALDI-MS analysis of the sodium lactate buffer (pH 5.0) and the water (pH
25 6.9) after 24 h incubation with the GIC containing 1.56% w/w CPP-ACP and control GIC revealed that the CPP could be detected in the pH 5.0 buffer after incubation with the CPP-ACP containing GIC only. The mass spectrum obtained was the same as that observed with standard CPP-ACP.

30 Conclusion

 Stabilized complexes of CPP-ACP were incorporated into the glass powder of a GIC and, in contrast to what would have been expected, at least some of the calcium ions, phosphate ions and CPP were not bound into the GIC matrix but were

released to produce a cement with superior physicochemical and anticariogenic properties.

A major reason for using GICs in a variety of clinical applications is their capacity to chemically bond to different surfaces such as enamel, dentin and resin composite (Akinmade and Nicholson, 1993). GICs are used routinely in conjunction with resin composites (Li *et al.*, 1996; Pereira *et al.*, 1998), in Atraumatic Restorative Treatment (ART) (Frencken *et al.*, 1996), in tunnel restorations (Svanberg, 1992) and in restoration of primary teeth (Frankenberger *et al.*, 1997). Bond strength, therefore, is an important property of the GIC. The mean microtensile bond strength value of the CPP-ACP-containing GIC was superior to that of the control GIC. The testing method used has been successfully used on specimens with different dentin thickness, dentinal tubule orientation and with disease-affected dentin specimens (Phrukkanon *et al.*, 1998). Therefore, factors such as the quality, depth and moisture of the dentin substrate (Burrow *et al.*, 1994; Tagami *et al.*, 1993) did not affect the results of this study.

The most common mode of failure in the adhesion between a GIC and the dentin during microtensile bond strength tests is Type 4, i.e., cohesive failure within the GIC (Tanumiharja *et al.*, 2000). This was the predominant mode of failure of the control GIC found in this study. The predominant mode of fracture for the CPP-ACP-containing GICs, was Type 2, i.e. partial cohesive failure in the GIC and partial adhesive failure between the GIC and the dentine.

With respect to the release of ions from the CPP-ACP-containing GIC and controls, it was shown that the fluoride release in sodium lactate buffer pH 5.0 was significantly higher than in water (pH 6.9). This finding has been previously reported for normal GICs (Forss, 1993; Kuhn and Wilson, 1985). However, in this study fluoride release was significantly higher from the CPP-ACP-containing GIC than the GIC-controls at both pH values which was an unexpected result. Without being bound by any theory, it would appear that the CPP-ACP promotes the release of fluoride ions from the GIC, probably by forming casein phosphopeptide-amorphous calcium fluoride phosphate (CPP-ACFP) complexes, which are released from the cement matrix.

Significantly more inorganic phosphate was released from the CPP-ACP GIC at both Ph values (5.0 and 6.9) than that released from the control GIC.

In this example, total rates of release from the CPP-ACP-containing GIC after 72 h at Ph 5.0 were $72.25 \pm 9.99 \mu\text{mol}/\text{mm}^2$ for fluoride, $1.85 \pm 0.1 \mu\text{mol}/\text{mm}^2$ for inorganic phosphate and $0.92 \pm 0.15 \mu\text{mol}/\text{mm}^2$ for calcium ions. The higher microtensile bond strength of the CPP-ACP-containing GIC and the capacity of the cement to release CPP-ACFP complexes indicates that the 1.56%-CPP-ACP-containing GIC was a superior restorative/base with an improved anticariogenic potential.

Example 2 **Remineralisation of dentine by release of CPP-ACFP from a GIC containing CPP-ACFP**

Freshly extracted and caries-free human third molars, with no cracks and defects, stored in normal saline solution were used to prepare two box-shaped cavities, 7 mm long x 3 mm wide x 1.5 mm deep, along the cemento-enamel junction of both mesial and distal surfaces, using a cylindrical diamond bur, high-speed turbine and air-water coolant. The cavity margins were finished with a slow-speed cylindrical diamond bur to achieve a cavo-surface angle as close as possible to 90°. The teeth were divided into two groups (A, B). Teeth from group A were restored with a self-curing GIC (Fuji IX GP capsulated, batch No. 140493, GC International, Tokyo, Japan), and teeth from group B, the experimental group, was restored using the same GIC plus 1.56% w/w CPP-ACP prepared as in Example 1. The GIC liquid and the powder:liquid ratio for all the specimens remained as for the commercial product. The materials were mixed at room temperature, placed into the cavities using a plastic spatula and allowed to set at 37° C and 100% RH for 1 h. The restorations were finished and polished with fine polishing discs (Soflex, 3M) under running water to ensure all margins are exposed, and the integrity of each cavo-surface margin was confirmed under a light microscope at 20x magnification.

The roots of the teeth containing the GIC restoration were cut using a slow-speed diamond saw under copious water spray. Two coats of nail varnish were applied to the entire tooth surface, leaving only a 1-mm window around the cavity margins. Each tooth was stored in an individual plastic vial containing 25 mL of acid buffer solution consisting of 2.2 mM calcium chloride, 2.2 mM sodium dihydrogen orthophosphate and 50 mM acetic acid at pH 5.0. The teeth were stored in the solution for four days, and the solution was refreshed every 24 h.

The specimens were removed from the demineralising solution, rinsed under tap water thoroughly and cut through the restorations with a water-cooled diamond saw microtome, to produce longitudinal sections which were ground to 100 μm thickness. The resulting slides were evaluated for lesion formation using

5 polarized-light microscopy with quinoline as imbibition medium (Fig. 1 and Fig. 2).

Figure 1 shows a substantial subsurface lesion in the dentine adjacent to the GIC restoration with very little protection being provided by the fluoride-releasing GIC. Fig. 2 on the other hand shows a poorly formed subsurface lesion with dramatic protection (remineralisation) provided by the release of CPP-ACFP

10 from the GIC. These results show that the inclusion of CPP-ACP into a fluoride-releasing GIC produces a remarkable ability to remineralize (repair) early stages of decay around GIC restorations.

Other advantages and modifications to the basic invention and its construction as described above will be apparent to those skilled in the art and all

15 modifications and adaptations are included in the scope of the invention.

TABLES

Table 1. Compressive strength (MPa) and net setting time (s) for CPP-ACP-containing GIC and controls

Table 5. Phosphate release from CPP-ACP-containing GIC and control at neutral and acidic pH

Period	Inorganic phosphate release ($\mu\text{mol}/\text{mm}^2$)			
	Water (pH 6.9)		Sodium Lactate (pH 5.0)	
	CPP-ACP GIC	Control GIC	CPP-ACP GIC	Control GIC
1 st 24 h	$0.36 \pm 0.07^{\text{a,b,c}}$	$0.02 \pm 0.00^{\text{d}}$	$0.88 \pm 0.15^{\text{b,c}}$	$0.53 \pm 0.05^{\text{d}}$
2 nd 24 h	$0.09 \pm 0.13^{\text{c}}$	$0.01 \pm 0.01^{\text{d}}$	$0.48 \pm 0.03^{\text{c}}$	$0.53 \pm 0.03^{\text{d}}$
3 rd 24 h	$0.02 \pm 0.01^{\text{c}}$	$0.01 \pm 0.01^{\text{d}}$	$0.48 \pm 0.05^{\text{c}}$	$0.49 \pm 0.03^{\text{d}}$
Total	$0.49 \pm 0.10^{\text{b,c}}$	$0.15 \pm 0.10^{\text{d}}$	$1.85 \pm 0.13^{\text{b,c}}$	$1.55 \pm 0.06^{\text{d}}$

15 ^a Mean \pm standard deviation, n = 6.

^b Significantly different ($p < 0.05$) from control value at the same pH.

^c Significantly different ($p < 0.05$) from CPP-ACP GIC value at different pH.

^d Significantly different ($p < 0.05$) from control value at different pH.

CLAIMS:

1. A composition for dental restoration including a dental restorative material and an effective amount of a casein phosphopeptide(CPP)-amorphous calcium phosphate (ACP) complex or casein phosphopeptide(CPP)-amorphous calcium fluoride phosphate (ACFP) complex.
5
2. A composition according to claim 1, wherein the CPP includes the amino acid sequence -Ser(P)-Ser(P)-Ser(P)-.
3. A composition according to either claim 1 or 2, wherein the ACP is formed under alkaline conditions.
- 10 4. A composition according to any one of claims 1 to 3, wherein the ACP is of the formula $\text{Ca}_3(\text{PO}_4)_2 \cdot x\text{H}_2\text{O}$, where $x \geq 1$.
5. A composition according to claim 1, wherein the ACFP is formed under alkaline conditions.
6. A composition according to either claim 1 or 5, wherein the ACFP is of the
15 formula $\text{Ca}_2\text{F}(\text{PO}_4) \cdot x\text{H}_2\text{O}$, where $x \geq 1$.
7. A composition according to claim 6, wherein the ACFP also contains ACP, wherein ACP and ACFP are in the ratio of $n:1$, where n is an integer ≥ 1 .
8. A composition according to any one of claims 1 to 7, wherein the dental restorative material is dental cement.
- 20 9. A composition according to claim 8, wherein the dental cement is a glass ionomer cement.
10. A composition according to any one of claims 1 to 9, wherein the effective amount of the CPP-ACP complex or CPP-ACFP complex is 0.01 to 80% by weight.
- 25 11. A composition according to claim 10 wherein the effective amount is 0.5 to 10% by weight.

12. A composition according to claim 11 wherein the effective amount is 1 to 5% by weight.
13. A composition according to any one of claims 1 to 12, having a pH from 2 to 10.
- 5 14. A composition according to claim 13, wherein the pH is from 5 and 9.
15. A composition according to claim 14, wherein the pH is from 7 and 9.
16. A method of manufacture of a composition according to any one of claims 1 to 15, wherein the method includes the addition of ACP or ACFP, and CPP to the dental restorative material.
- 10 17. A method of manufacture of a composition according to any one of claims 1 to 15, wherein the method includes the addition of CPP-ACP complex or CPP-ACFP complex to the dental restorative material.
18. Use of a composition according to any one of claims 1 to 15, or manufactured by the method according to either claim 16 or 17, for the preparation of a medicament intended for the treatment and/or prevention of dental caries in animals.
- 15 19. Use according to claim 18 wherein the animal is human.
20. A method of treatment and/or prevention of dental caries in animals including providing the composition according to any one of claims 1 to 15, or manufactured by the method according to either claim 16 or 17, and applying to teeth in an animal in need of treatment and/or prevention.
- 20 21. A method according to claim 20, wherein the animal is human.
22. A kit of parts including (a) dental restorative material and (b) CPP-ACP complex and/or CPP-ACFP complex, together with instructions for their use for the preparation of a composition according to any one of claims 1 to 15.
- 25 23. A kit of parts including (a) dental restorative material, (b) casein phosphopeptides (c) calcium ions and (d) phosphate ions, together with

instructions for their use for the preparation of a composition according to any one of claims 1 to 15.

24. A kit of parts according to claim 23, further including flouride ions.
25. A composition according to claim 1, substantially as described herein with
5 reference to either example.
26. A method of manufacture according to claim 16, substantially as described herein with reference to either example.
27. Use according to claim 18, substantially as described herein with reference to either example.
- 10 28. A method of treatment and/or prevention of dental caries according to claim 20, substantially as described herein with reference to either example.
29. A kit of parts according to any one of claims 22 to 24, substantially as described herein with reference to either example.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/AU02/00632

A. CLASSIFICATION OF SUBJECT MATTER

Int. Cl. ⁷: A61K 6/033

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

WPAT & Medline: casein phosphopeptide, calcium phosphate, calcium fluoride phosphate, dental, teeth, tooth, glass ionomer

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	WO 98/40406 A (THE UNIVERSITY OF MELBOURNE ET AL) 17 September 1998 See page 5 lines 6-19.	22-24,29
Y	Akinmade A.O et al. "Glass-ionomer cements as adhesives. Part 1 Fundamental aspects and their clinical relevance." Journal of Materials Science: Materials in Medicine Vol 4 (1993) p 95-101. See page 95-97.	22-24,29

☐ Further documents are listed in the continuation of Box C ☒ See patent family annex

<p>* Special categories of cited documents:</p> <p>"A" document defining the general state of the art which is not considered to be of particular relevance</p> <p>"E" earlier application or patent but published on or after the international filing date</p> <p>"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)</p> <p>"O" document referring to an oral disclosure, use, exhibition or other means</p> <p>"P" document published prior to the international filing date but later than the priority date claimed</p>		<p>"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention</p> <p>"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone</p> <p>"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art</p> <p>"&" document member of the same patent family</p>
